Supplement Section B: Inferential statistics

In this document;

- **B1:** Comprehensive models with exploratory variables and variable exclusion process
- **B2:** Unsplit models (without stimulus type separation)
- **B3:** Complete models including control condition
- **B4:** Factorial 2x2 models
- **B5:** Normality assessments and Model assumptions
- **B6:** Power Analysis
- **B7:** Expected vs. Observed ratings of item photographs
- **B8:** Walking Proficiency in the Video Stimuli

In the .Pdf output file you may find only the outputs generated by the analysis code, in order to keep the supplementary files as concise as possible. However the full code is available on https://github.com/Rezvani-S/Costly-Beauty-ShoeStudy.git (https://github.com/Rezvani-S/Costly-Beauty-ShoeStudy.git)

1. Required Packages

2. Data Import and Preparation

PART I: Supplement B1: Comprehensive models with exploratory variables and variable exclusion process

3. Data Cleaning and Preparation

4. Comprehensive Attractiveness Model

A comprehensive linear mixed-effects model for attractiveness was constructed, including all potential variables:

```
## Linear mixed model fit by REML. t-tests use Satterthwaite's method [
## lmerModLmerTest]
## Formula: Rating ~ Condition + sex + monthlyincome + merged_score_zscore +
##     Stimuli_Type + (1 | block/Model) + (1 | code)
##    Data: body_df_attract
##
## REML criterion at convergence: 47192.8
##
## Scaled residuals:

7. AIC and BIC Comparison for Model Selection

To further evaluate model selection, AIC and BIC values were compared between the comprehensive and simplified models:

```
## AIC and BIC comparison for Attractiveness models:
```

```
##           Model      AIC      BIC
## 1 Comprehensive 47222.76 47335.34
## 2        Simple 50862.96 50923.01
```

```
##
## AIC and BIC comparison for Wealth models:
```

```
##           Model      AIC      BIC
## 1 Comprehensive 43794.64 43907.19
## 2        Simple 45142.00 45202.03
```

PART II: Supplement B2: Unsplit models (without stimulus type separation)

Data Cleaning and Preparation

8. Attractiveness Model with Interaction

A linear mixed-effects model for attractiveness was constructed including the interaction between Condition and Stimuli_Type:

```
## Linear mixed model fit by REML. t-tests use Satterthwaite's method [
## lmerModLmerTest]
## Formula: Rating ~ Condition * Stimuli_Type + (1 | block/Model) + (1 |
##     code)
##    Data: body_df_attract
##
## REML criterion at convergence: 47670.8
##
## Scaled residuals:
##     Min      1Q  Median      3Q     Max
## -5.1231 -0.6220 -0.0116  0.6116  4.3467
##
## Random effects:
##  Groups      Name        Variance Std.Dev.
##  code        (Intercept) 1.7190   1.3111

10. Combined Plot: Condition × Dimension × Stimuli_Type

A combined plot was created to visualize the interaction between Condition, Dimension, and Stimuli_Type:

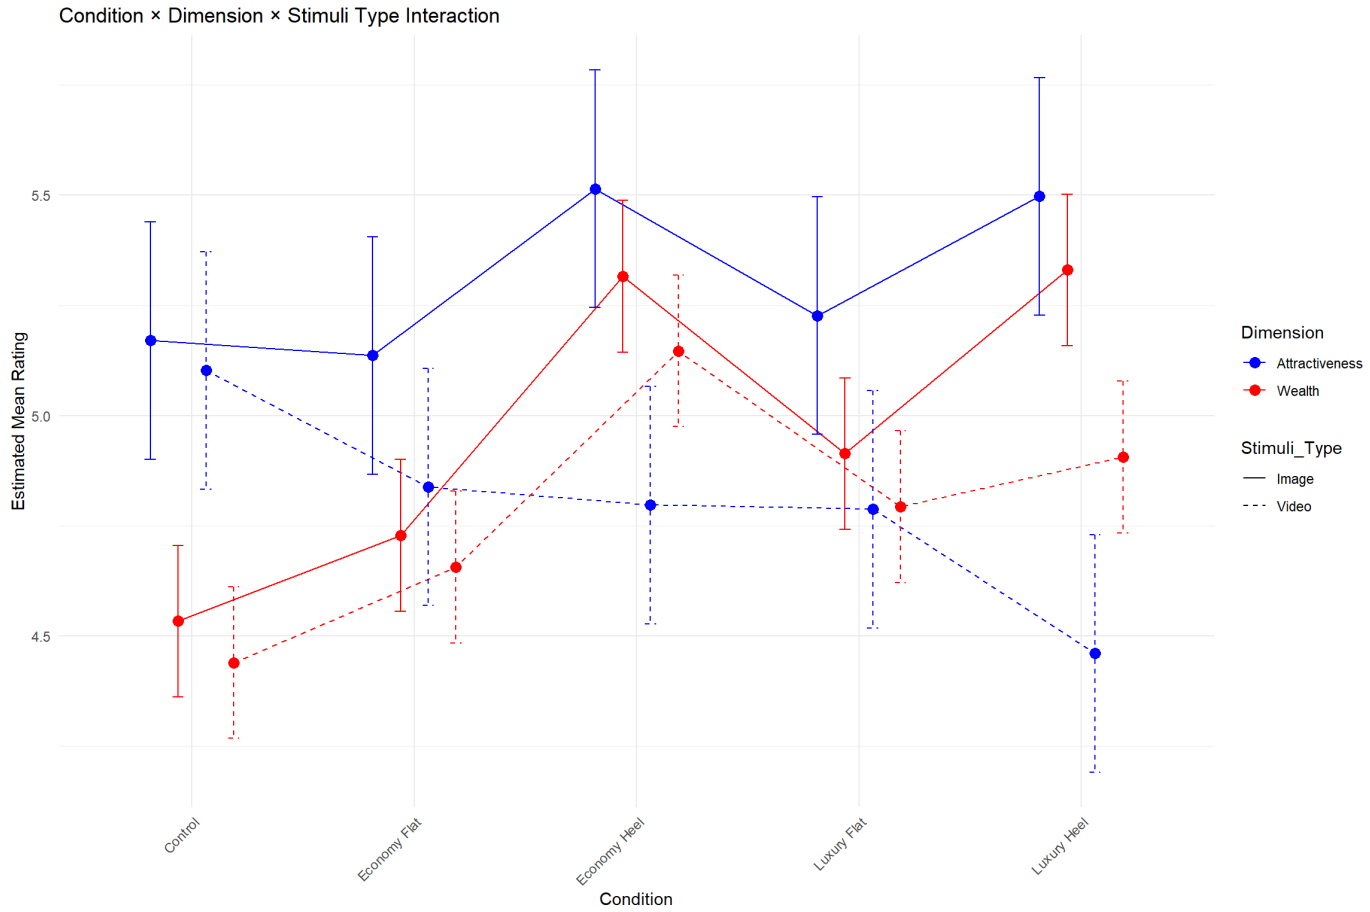

Figure B2.3. Three-way interaction between footwear condition, dimension (attractiveness vs. wealth), and stimulus type. Solid lines represent image stimuli; dashed lines represent video stimuli. Error bars represent 95% confidence intervals.

PART III: Supplement B3: Complete models including control condition (Split by StimuliType)

11. Models for Image Stimuli Only

17.6 Visualization: Effect Sizes Across Models

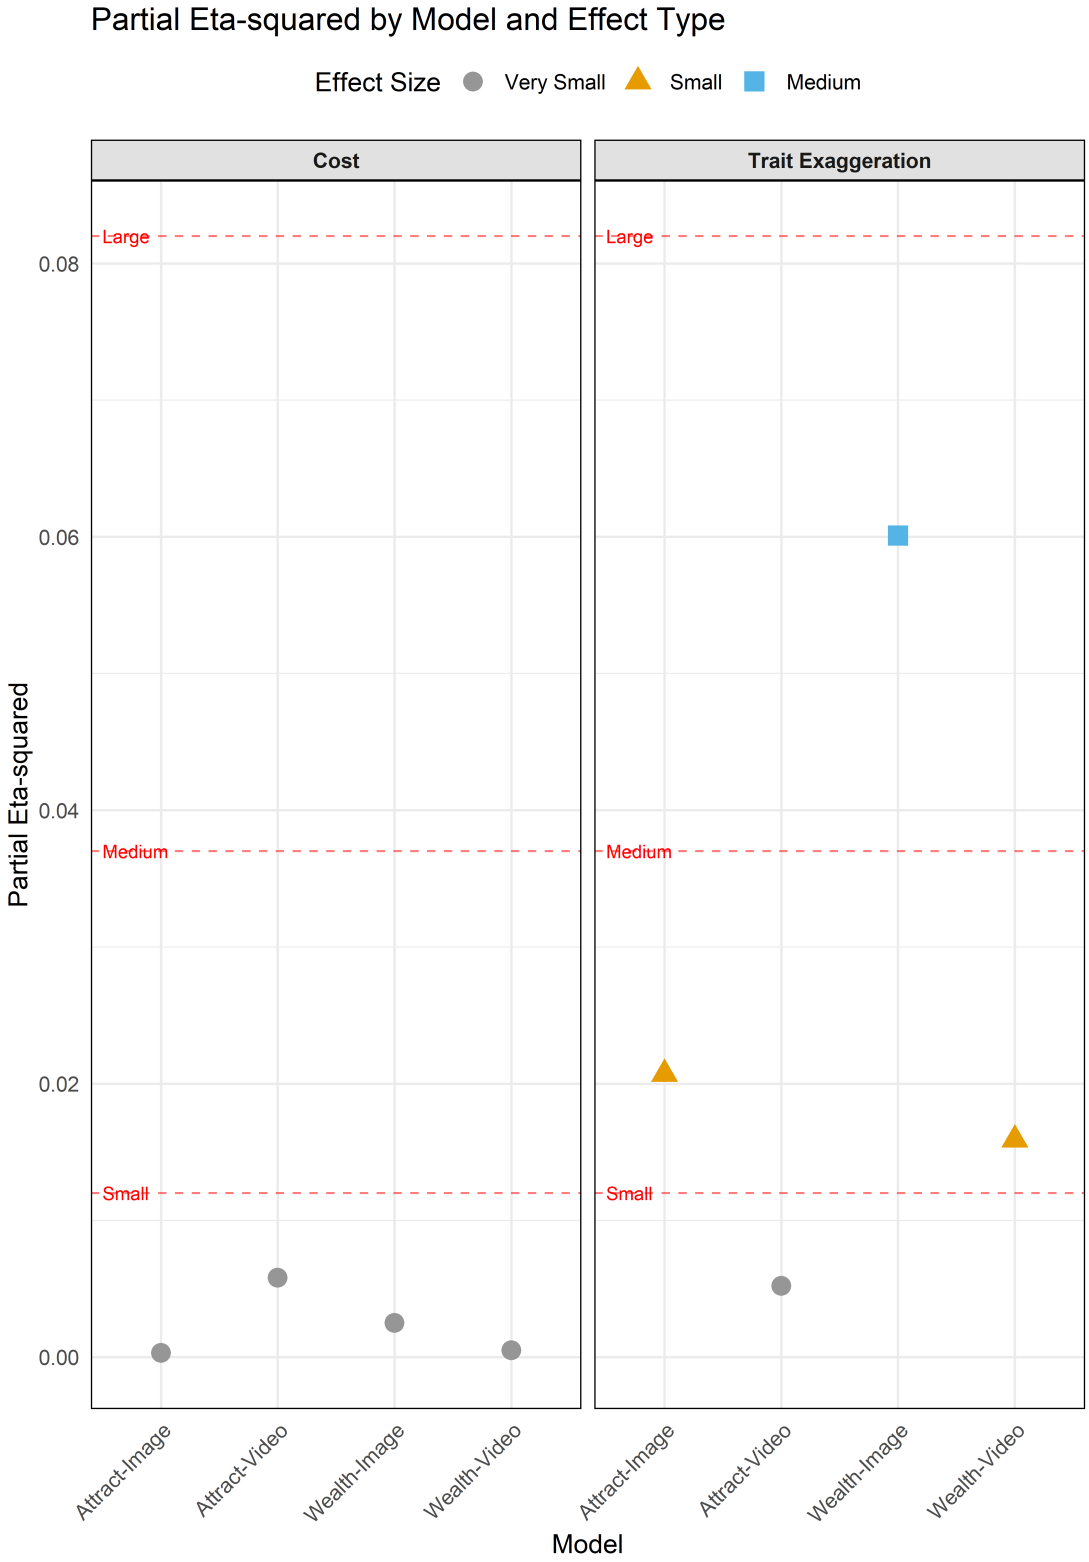

Figure B4.3. Partial Eta-squared effect sizes for main effects across all 2×2 factorial models. Dashed reference lines indicate small (0.012), medium (0.037), and large (0.082) effect size thresholds. For Effect Size Interpretation Guidelines see Supplement Section A3.

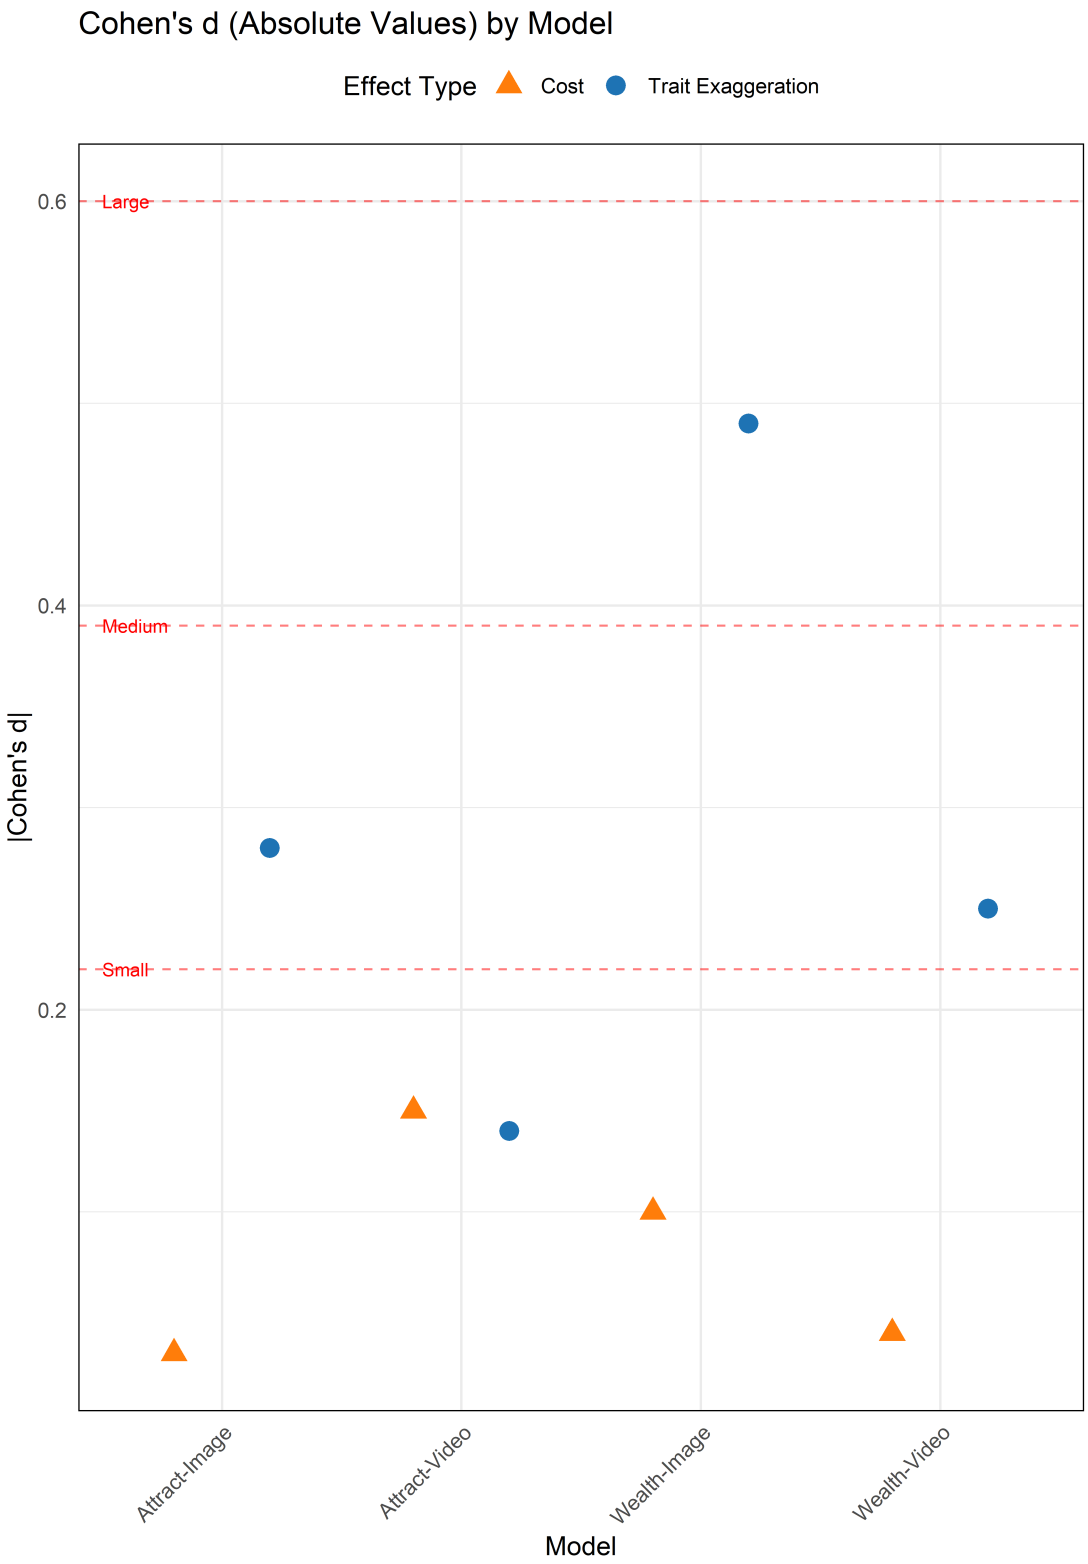

Figure B4.4. Cohen's d effect sizes (absolute values) for cost and trait exaggeration main effects across all models. Dashed reference lines indicate small (0.22), medium (0.39), and large (0.60) effect size thresholds.For Effect Size Interpretation Guidelines see Supplement Section A3.

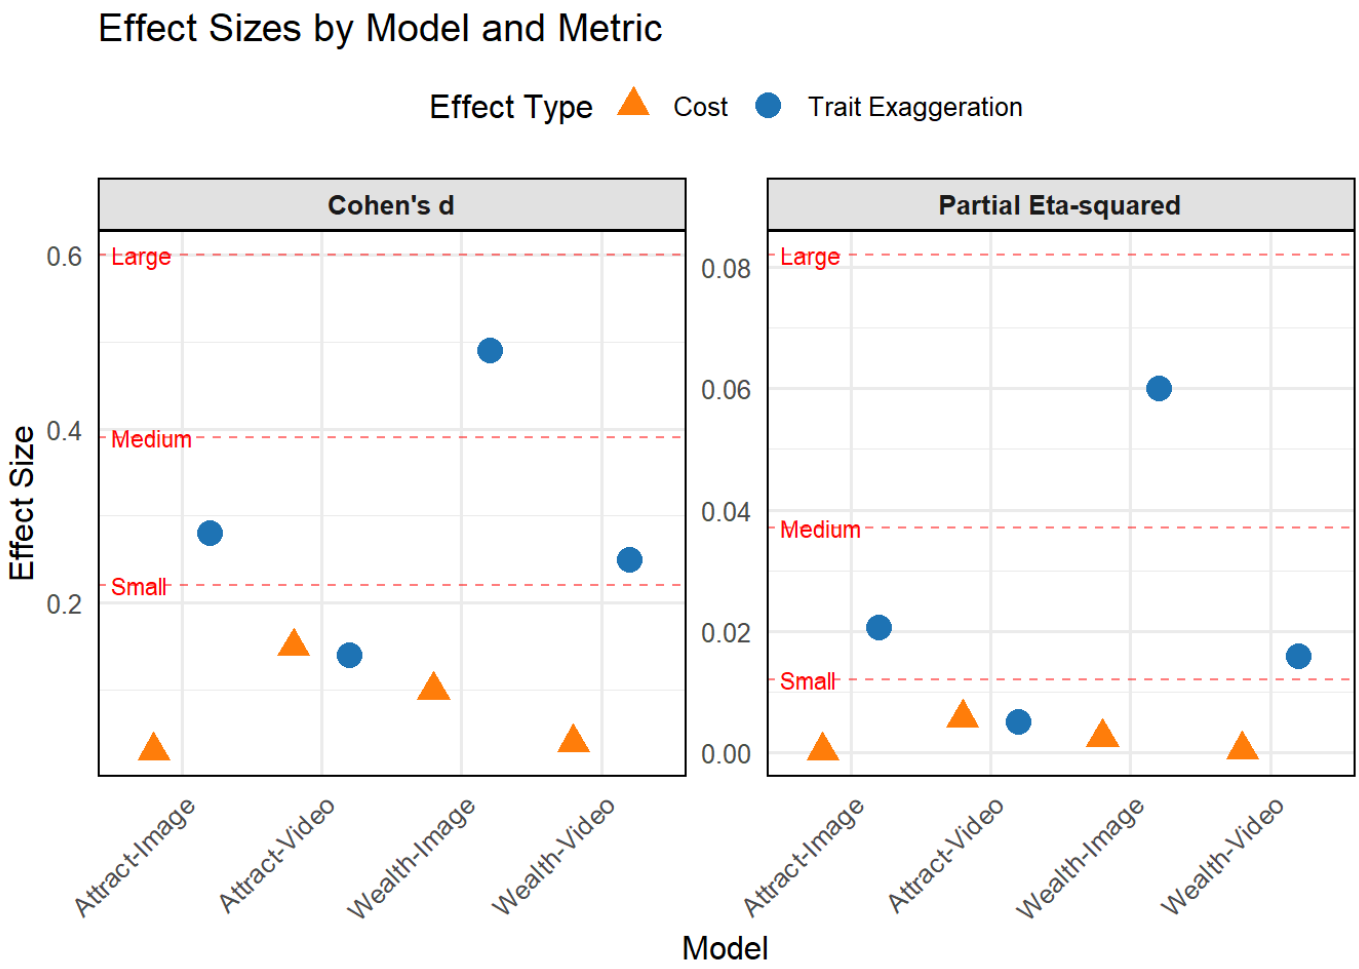

Figure B4.5. Effect sizes for main effects across all 2×2 factorial models, shown as Cohen's d (left panel) and partial Eta-squared (right panel). Dashed reference lines indicate small, medium, and large effect size thresholds for each metric (d: 0.22, 0.39, 0.60; Eta-squared: 0.012, 0.037, 0.082). For Effect Size Interpretation Guidelines see Supplement Section A3.

PART V: Supplement B5: Normality Assumption Checks for Mixed-Effects Models with Nested Structure

20. Function to calculate standardized residuals (Pearson residuals scaled by their standard deviation)

21. Function to Check normality of random intercepts for each grouping factor

22. Function to perform formal normality tests

23. applying the functions to the models from section III

```
## === ATTRACTIVENESS IMAGE MODEL NORMALITY CHECKS ===
```

```
## Note: Shapiro-Wilk performed on random sample of 5000 residuals
## Random effects for block have zero variance (boundary fit) - skipping normality test
```

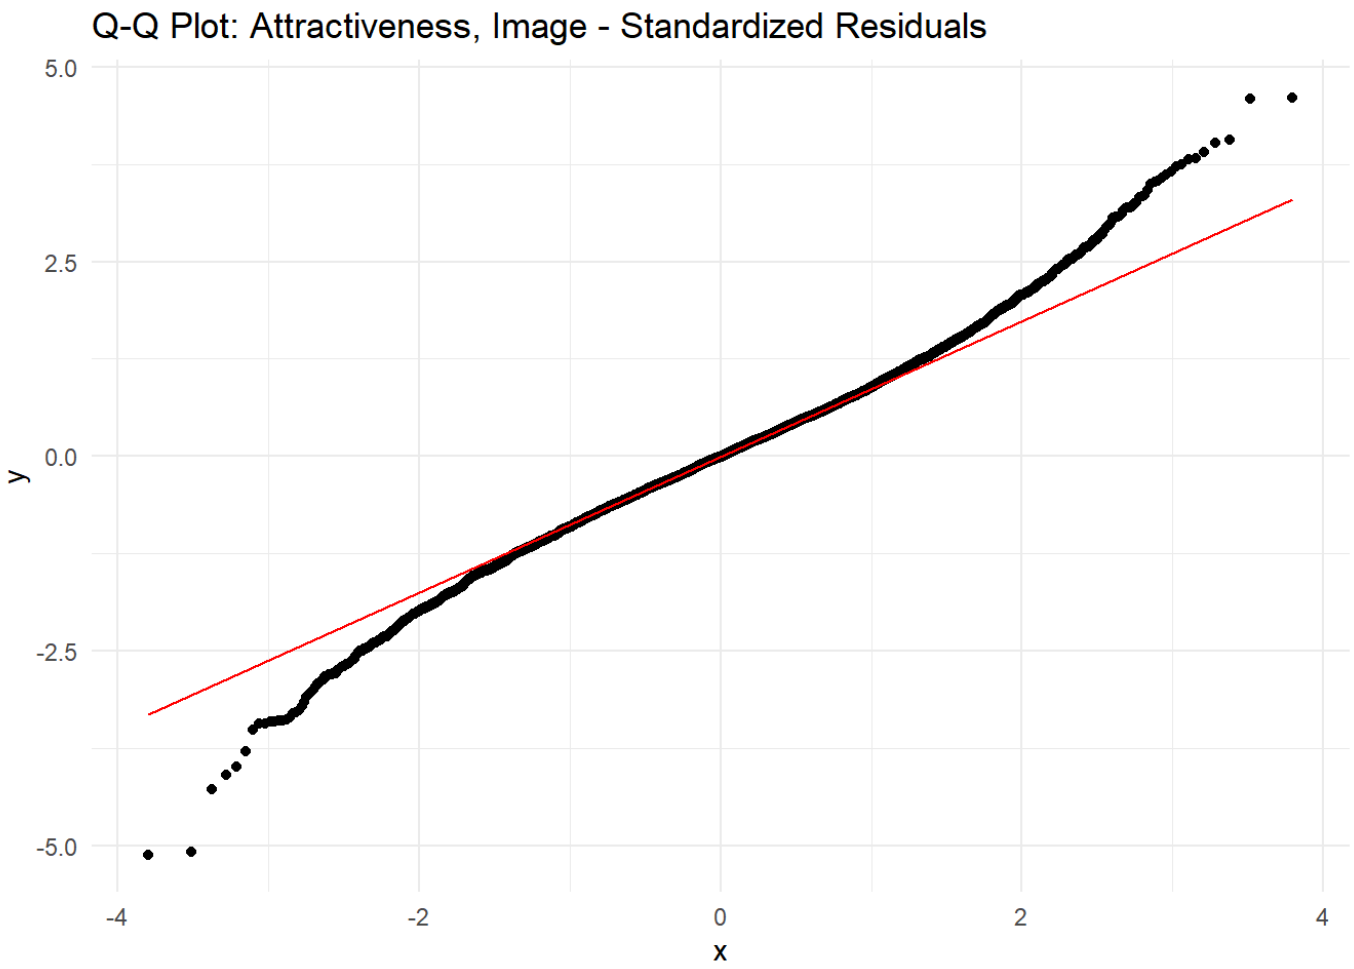

```
##
## === WEALTH MODEL NORMALITY CHECKS ===
```

```
## Note: Shapiro-Wilk performed on random sample of 5000 residuals
## Random effects for block have zero variance (boundary fit) - skipping normality test
```

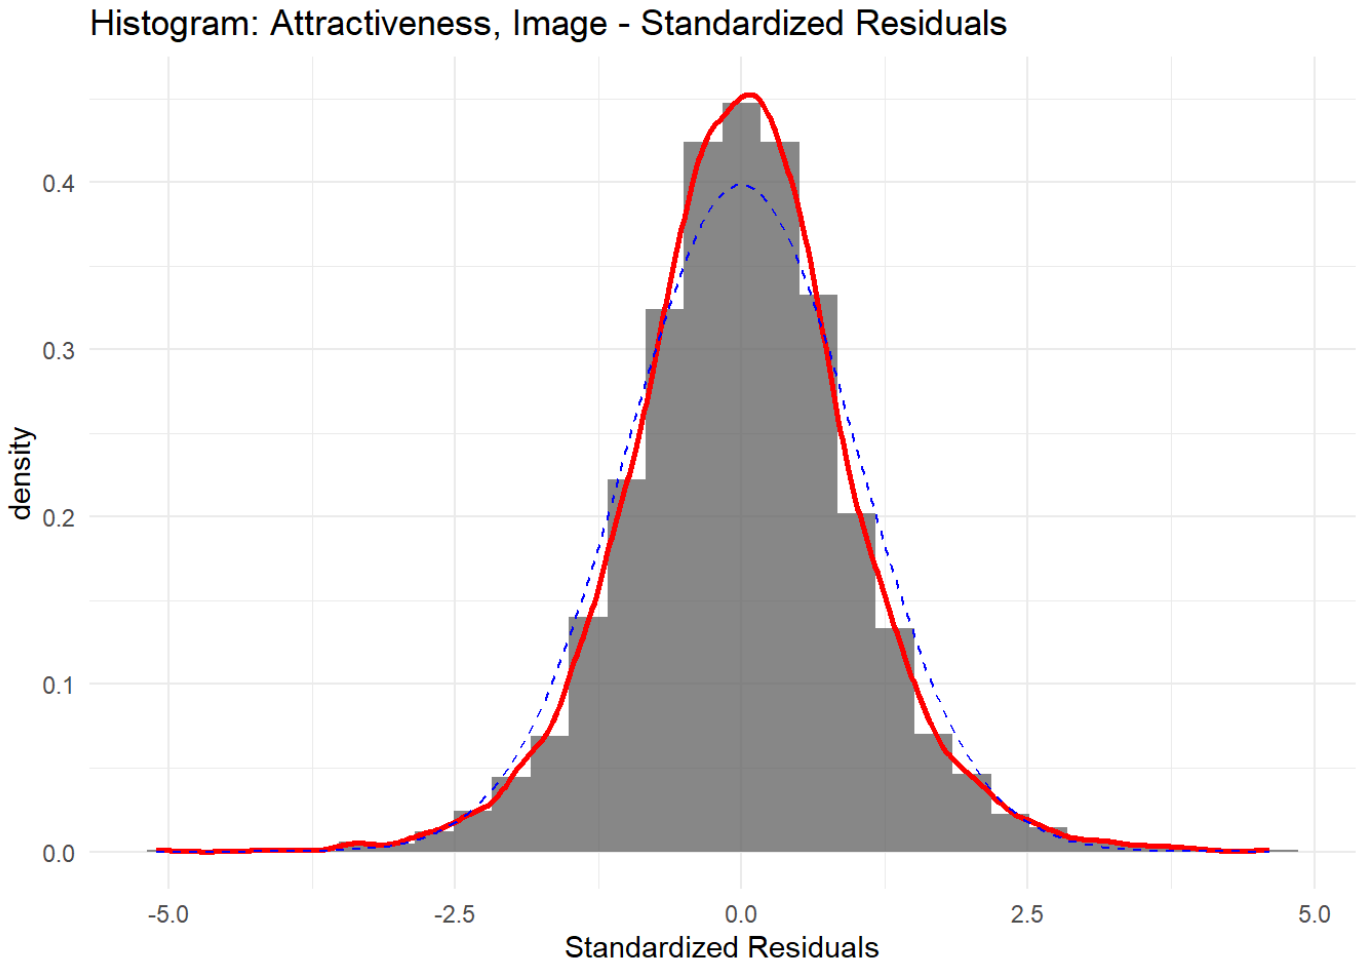

24. Visualizing the results

```
## Model: Attractiveness, Image
## Residuals Shapiro-Wilk: W = 0.9901 , p = 0
## Residuals Anderson-Darling: A = 11.1158 , p = 0
## Random Effects Tests:
##    code : W = 0.9926 , p = 0.1828
##    Model:block : W = 0.9782 , p = 0.4253
##    block : Test not performed - Zero variance
```

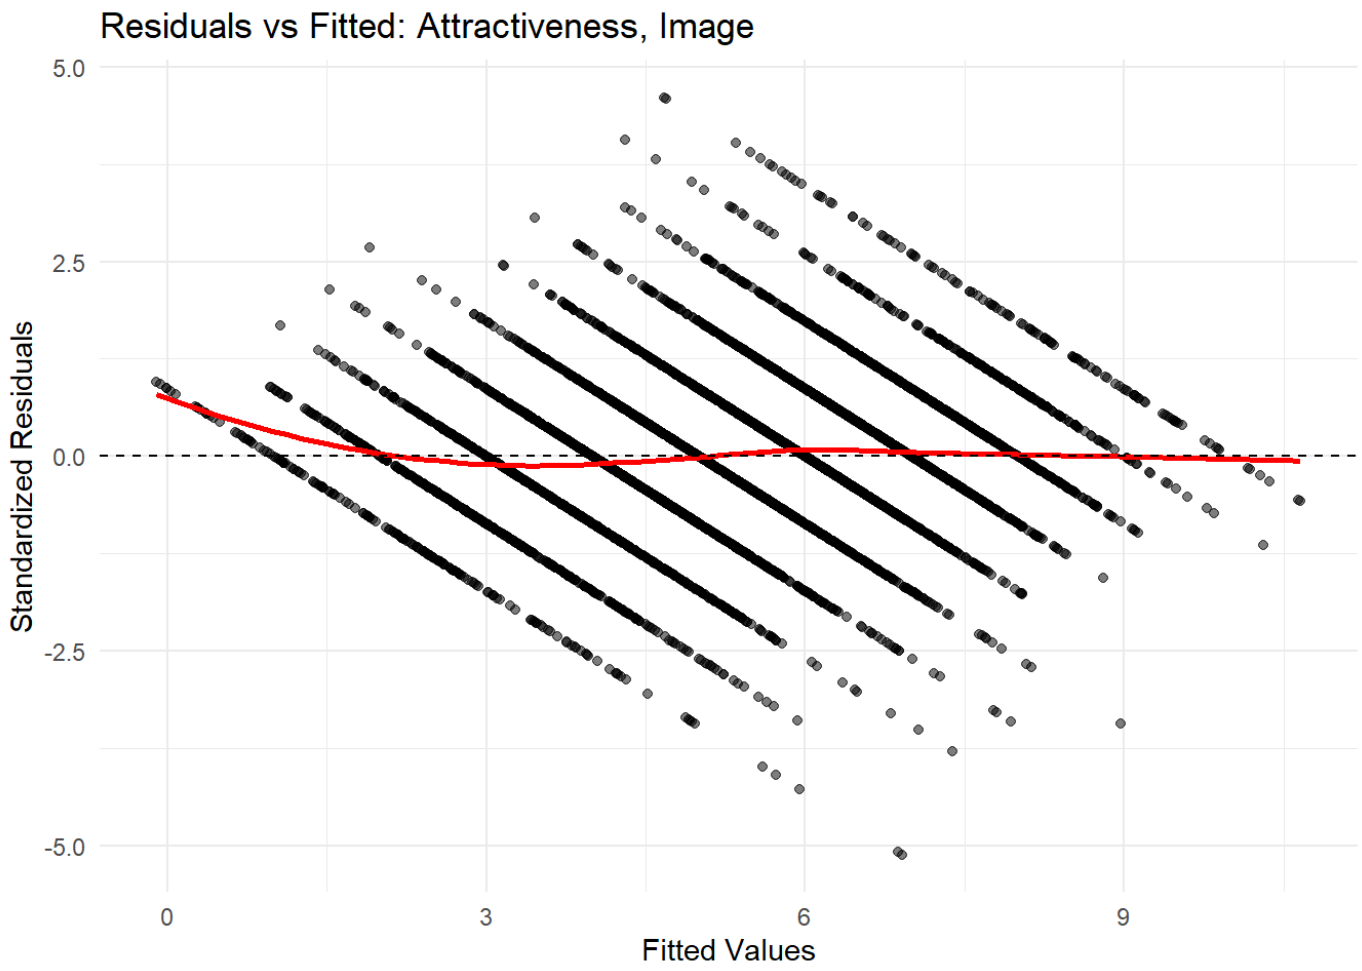

```
## Model: Wealth, Image
## Residuals Shapiro-Wilk: W = 0.9867 , p = 0
## Residuals Anderson-Darling: A = 22.2178 , p = 0
## Random Effects Tests:
##    code : W = 0.9833 , p = 0.0024
##    Model:block : W = 0.9833 , p = 0.6496
##    block : Test not performed - Zero variance
```

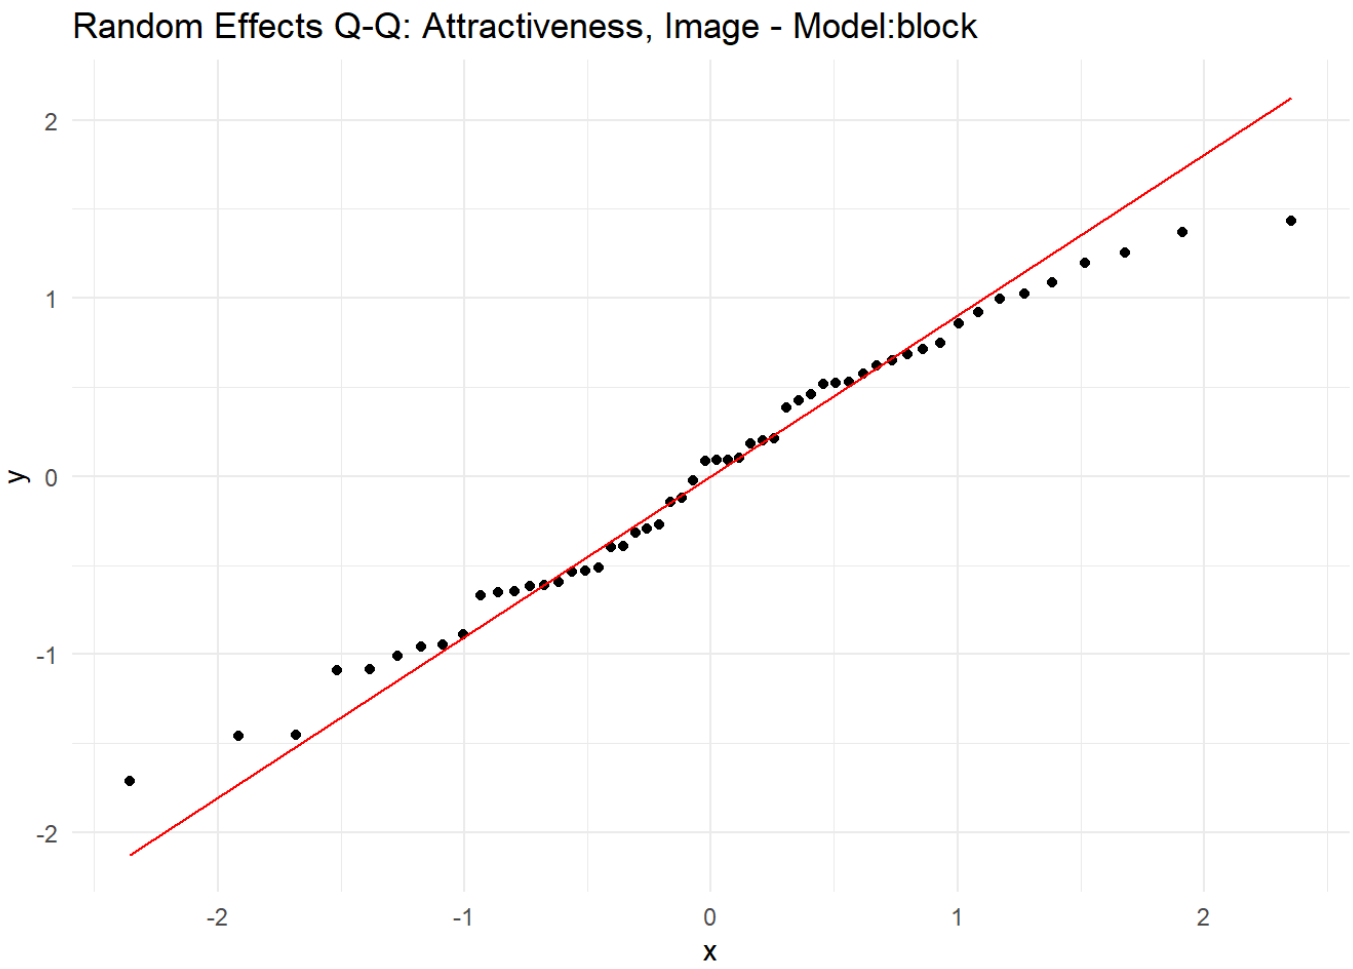

```
## Figure B5.1. Q-Q plot of standardized residuals for attractiveness ratings (image stimul
i).
##     Points closely following the reference line (red),
##     indicate approximate normality of residuals.
```

```
## Figure B5.2. Histogram of standardized residuals for attractiveness ratings (image stimul
i).
##     Red line shows kernel density estimate;
##     blue dashed line shows theoretical normal distribution (μ=0, σ=1).
```

```
## Figure B5.3. Standardized residuals versus fitted values for attractiveness ratings (image
stimuli).
##     Red loess curve and horizontal reference line assess homoscedasticity assumption.
##     No systematic patterns indicate appropriate model fit.
```

```
## Figure B5.4. Q-Q plot of random intercepts for Model:block grouping factor (attractivenes
s, image stimuli).
##     Assesses normality assumption for nested random effects structure.
```

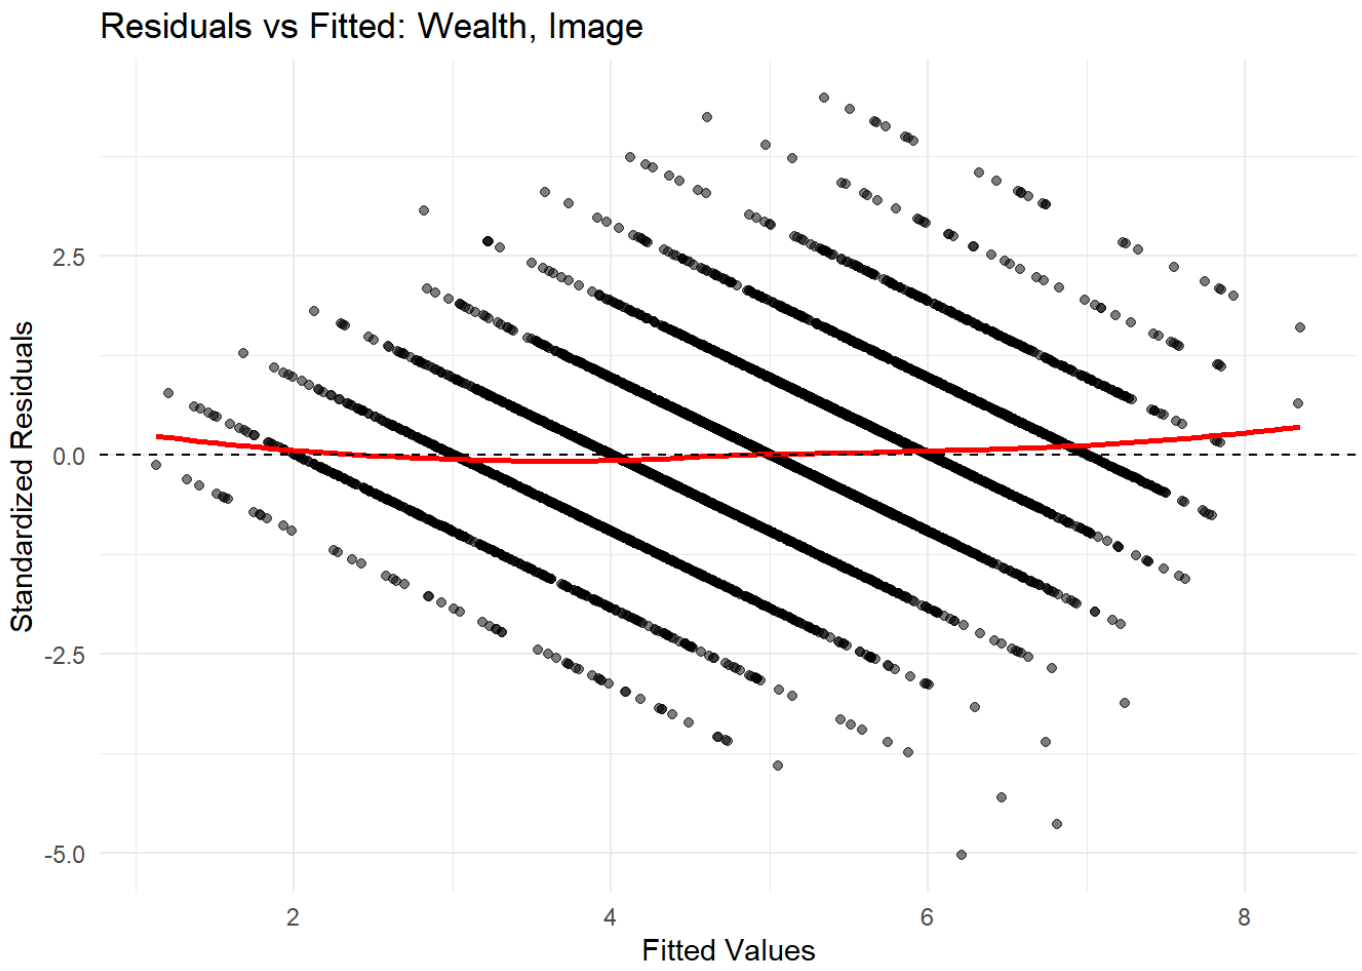

```
## Figure B5.5. Q-Q plot of random intercepts for rater (code) grouping factor (attractivenes
s, image stimuli).
##     Assesses normality assumption for individual rater effects.
```

```
## Figure B5.6. Q-Q plot of standardized residuals for wealth perception ratings (image stimu
li).
##     Points closely following the reference line (red),
##     indicate approximate normality of residuals.
```

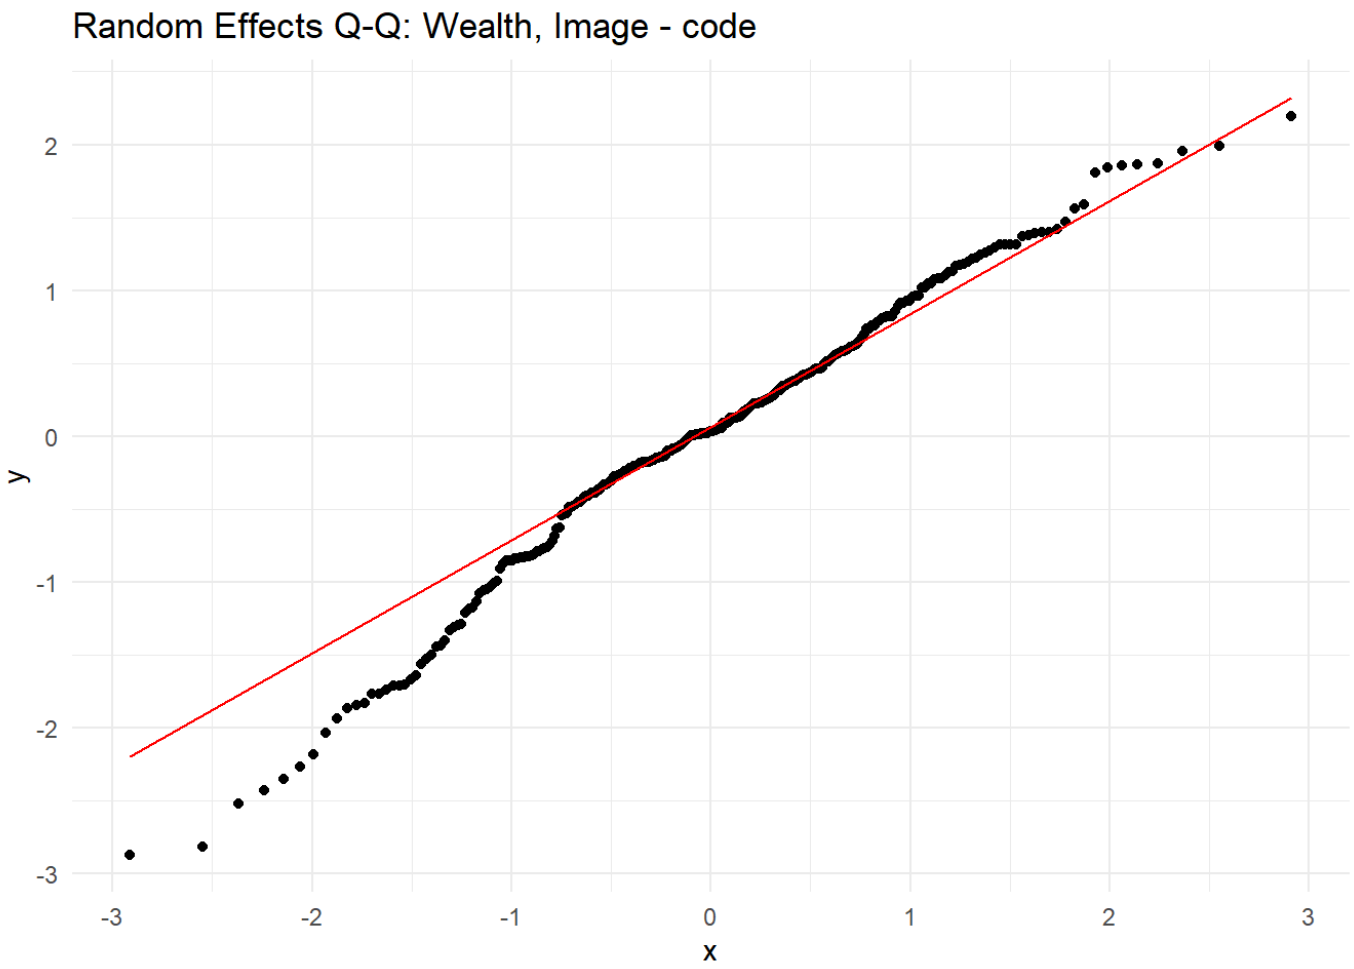

Figure B5.7. Histogram of standardized residuals for wealth perception ratings (image stimuli).
Red line shows kernel density estimate;
blue dashed line shows theoretical normal distribution (μ=0, σ=1).

```
## Figure B5.8. Standardized residuals versus fitted values for wealth perception ratings (im
age stimuli).
##     Red loess curve and horizontal reference line assess homoscedasticity assumption.
```

```
## Figure B5.9. Q-Q plot of random intercepts for Model:block grouping factor (wealth, image
stimuli).
##     Assesses normality assumption for nested random effects structure.
```

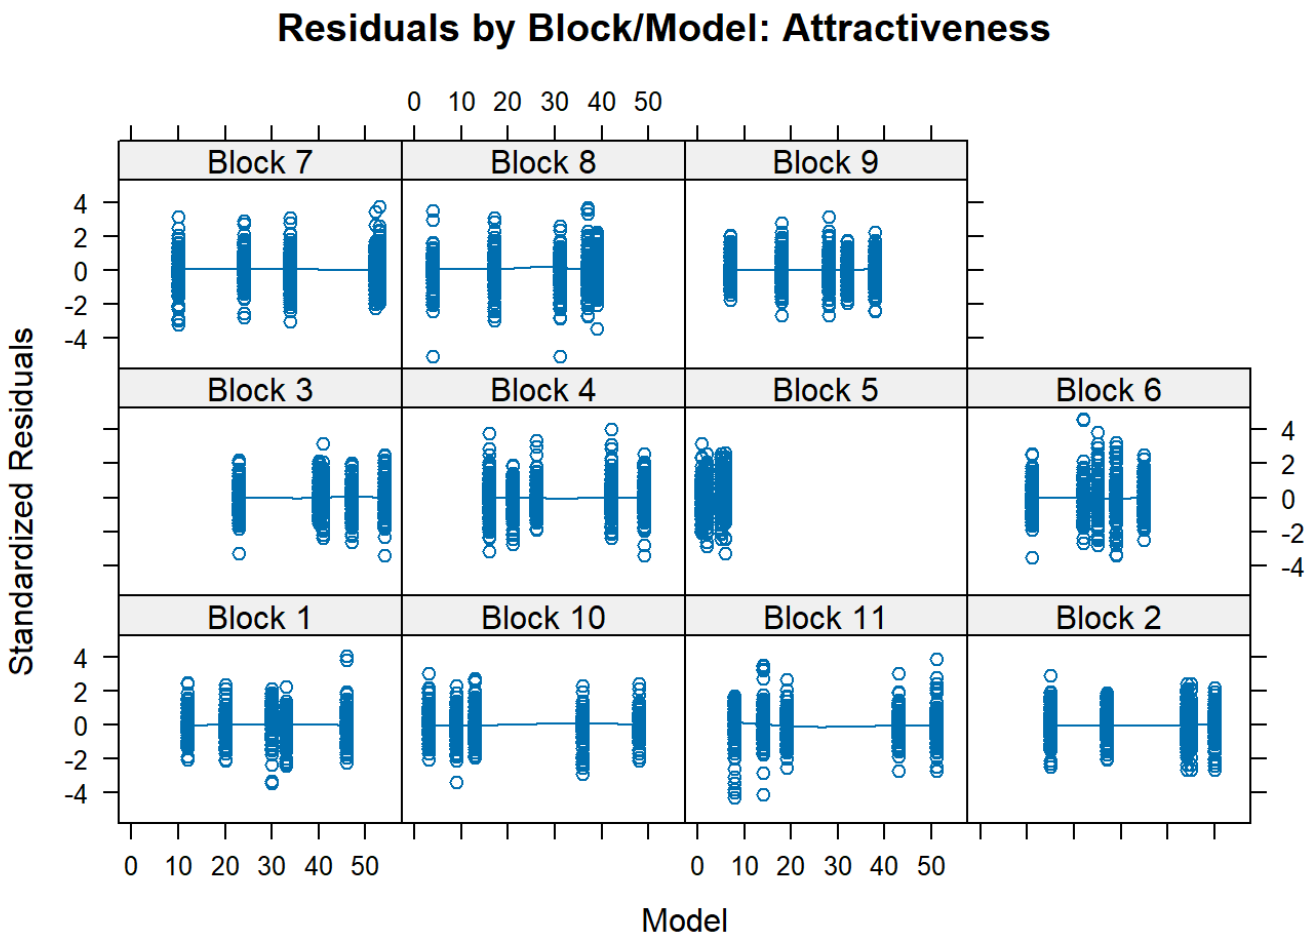

```
## Figure B5.10. Q-Q plot of random intercepts for rater (code) grouping factor (wealth, imag
e stimuli).
##     Assesses normality assumption for individual rater effects.
```

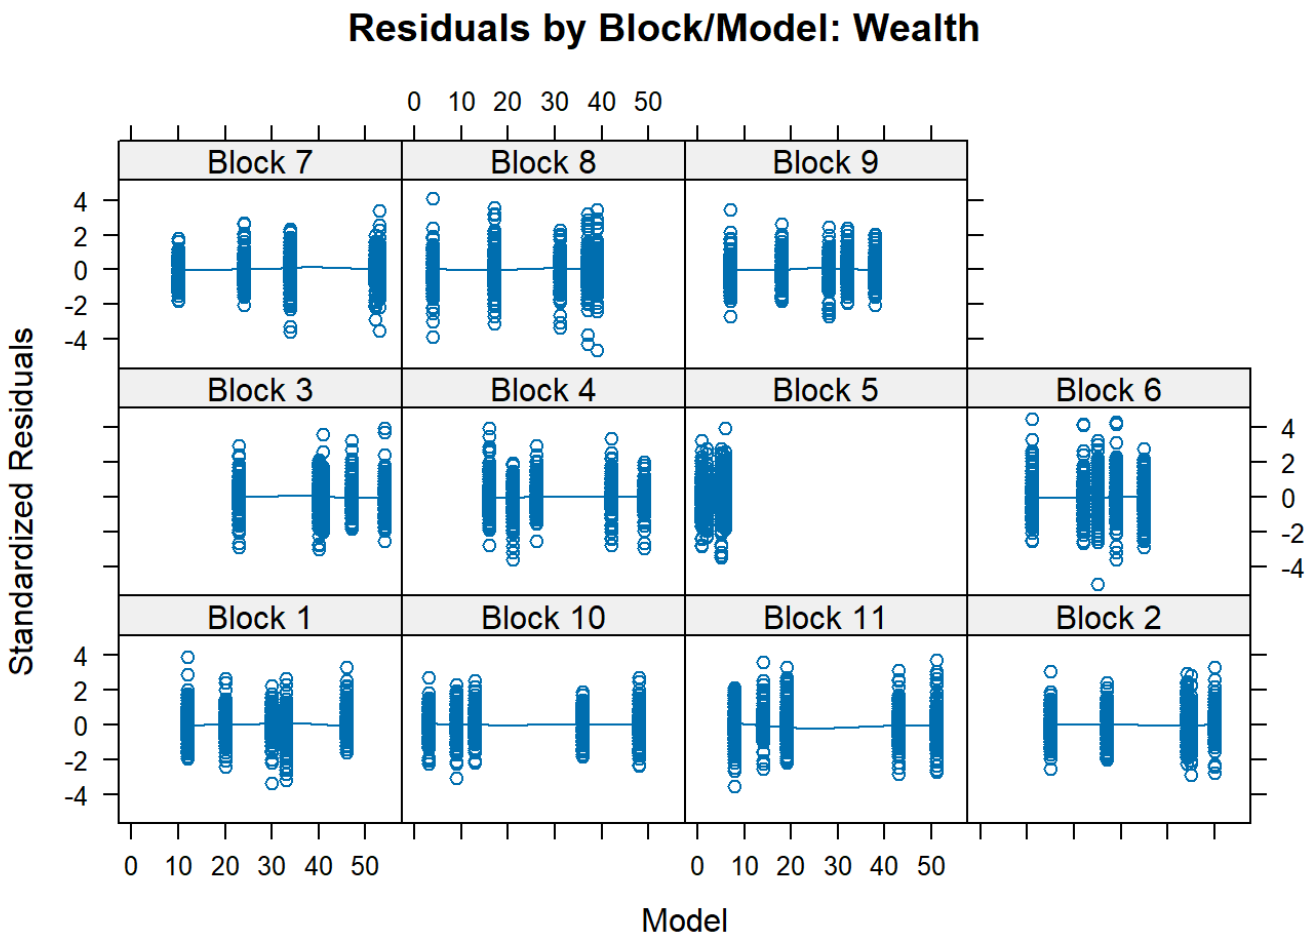

25. Diagnostic for Boundary fits and random effects variance

```
## === RANDOM EFFECTS EXAMINATION: Attractiveness ===

PART VII: Supplement B7: Expected versus Observed Ratings of Isolated Item Photographs

At the end of each rating session, participants additionally viewed standardised close-up photographs of the four experimental footwear items (Economy Flat, Economy Heel, Luxury Flat, Luxury Heel), presented independently of any model, and rated on the same Likert scales responding to estimate the appearance of attractiveness and wealth of an average hypothetical user. These isolated item ratings provide an **Expected** score, which can be contrasted with the **Observed** score obtained when the corresponding item was actually worn by a stimulus model. This section reports the data preparation, comparison, and inferential testing of these Expected versus Observed difference scores.

The Expected and Observed difference scores are defined as follows:

Expected [per item] = Isolated item-photograph rating − Control condition mean (image stimuli)
Observed [per condition] = Worn-item condition mean rating − Control condition mean

Both scores are referenced against the same control (no footwear) baseline, so that a divergence between Expected and Observed indicates that the isolated appraisal of an item over- or under-predicts its effect once embodied by a person.

26. Data Preparation for the Expected versus Observed Comparison

This section reuses `body_data`, as prepared in Section 2, without re-importing or re-cleaning the source file.

27. Paired-Samples Comparisons: Expected versus Observed Differences (Overall Sample)

Paired-samples *t*-tests were conducted for each condition, separately for the Attractiveness and Wealth dimensions and for image and video stimuli, testing whether the Expected difference score (isolated item photograph) differed statistically significantly from the Observed difference score (worn item).

Attractiveness (Image Stimuli): Expected vs. Observed Differences

	Condition	t_value	df	p_value	mean_diff	significance
EF.t	Economy Flat	-11.200	262	0.0000	-1.455	***
EH.t	Economy Heel	2.065	262	0.0399	0.315	*

LH.t	Luxury Heel	11.224	262	0.0000	1.711	***

28. Effect Sizes (Cohen’s d) for Expected versus Observed Comparisons

Effect Sizes: Attractiveness (Image Stimuli)

Condition	Cohens_d
Economy Flat	-0.691
Economy Heel	0.127

Condition	Cohens_d
Luxury Flat	-0.549
Luxury Heel	0.172

Effect Sizes: Attractiveness (Video Stimuli)

Condition	Cohens_d
Economy Flat	-0.550
Economy Heel	0.386
Luxury Flat	-0.382
Luxury Heel	0.522

Effect Sizes: Wealth (Image Stimuli)

Condition	Cohens_d
Economy Flat	-0.461
Economy Heel	0.268
Luxury Flat	-0.060
Luxury Heel	0.619

Effect Sizes: Wealth (Video Stimuli)

Condition	Cohens_d
Economy Flat	-0.466
Economy Heel	0.276
Luxury Flat	-0.045
Luxury Heel	0.692

29. 2×2 Factorial Analysis of Expected Scores (Trait Exaggeration × Cost)

To formally test whether the ordinal pattern visible in the Expected scores conforms to the hypothesized structure (H1A: Trait Exaggeration enhances Attractiveness; H1B: Cost enhances Wealth; H2: Trait Exaggeration × Cost interaction), a 2×2 factorial linear mixed-effects model was fitted to the Expected scores for each dimension, mirroring the model specification used for the Observed data in Supplement B4 (`Rating ~ Trait_Exaggeration * Cost`). A single random intercept for participant was retained; the `(1 | block/Model)` term used in B4 was omitted here, as the isolated item photographs were not associated with a specific stimulus model or presentation block. Because the Cost main effect on the Wealth model directly indexes whether participants correctly distinguished the luxury and economy items in isolation, this analysis additionally serves as a manipulation check on the cost manipulation; analogously, the Trait Exaggeration main effect on the Attractiveness model serves as a manipulation check on the heel manipulation.

Effect Sizes for the Expected-Score Factorial Models

Effect sizes were computed with the same procedures and benchmarks as in Section 17 (Cohen's *d* as the estimated marginal mean difference divided by the residual standard deviation of the model; partial η² from the ANOVA sums of squares). Because the Expected-score models contain a single random intercept for participant, the residual standard deviation is the within-participant residual and is not directly equivalent to that of the Observed-score models in B4.

31. Visualization of Expected versus Observed Differences

The following plots follow the visual conventions established in Section B4 (`theme_minimal` , bordered facet panels, top-aligned bold legend) to maintain a consistent style across the supplementary analyses.

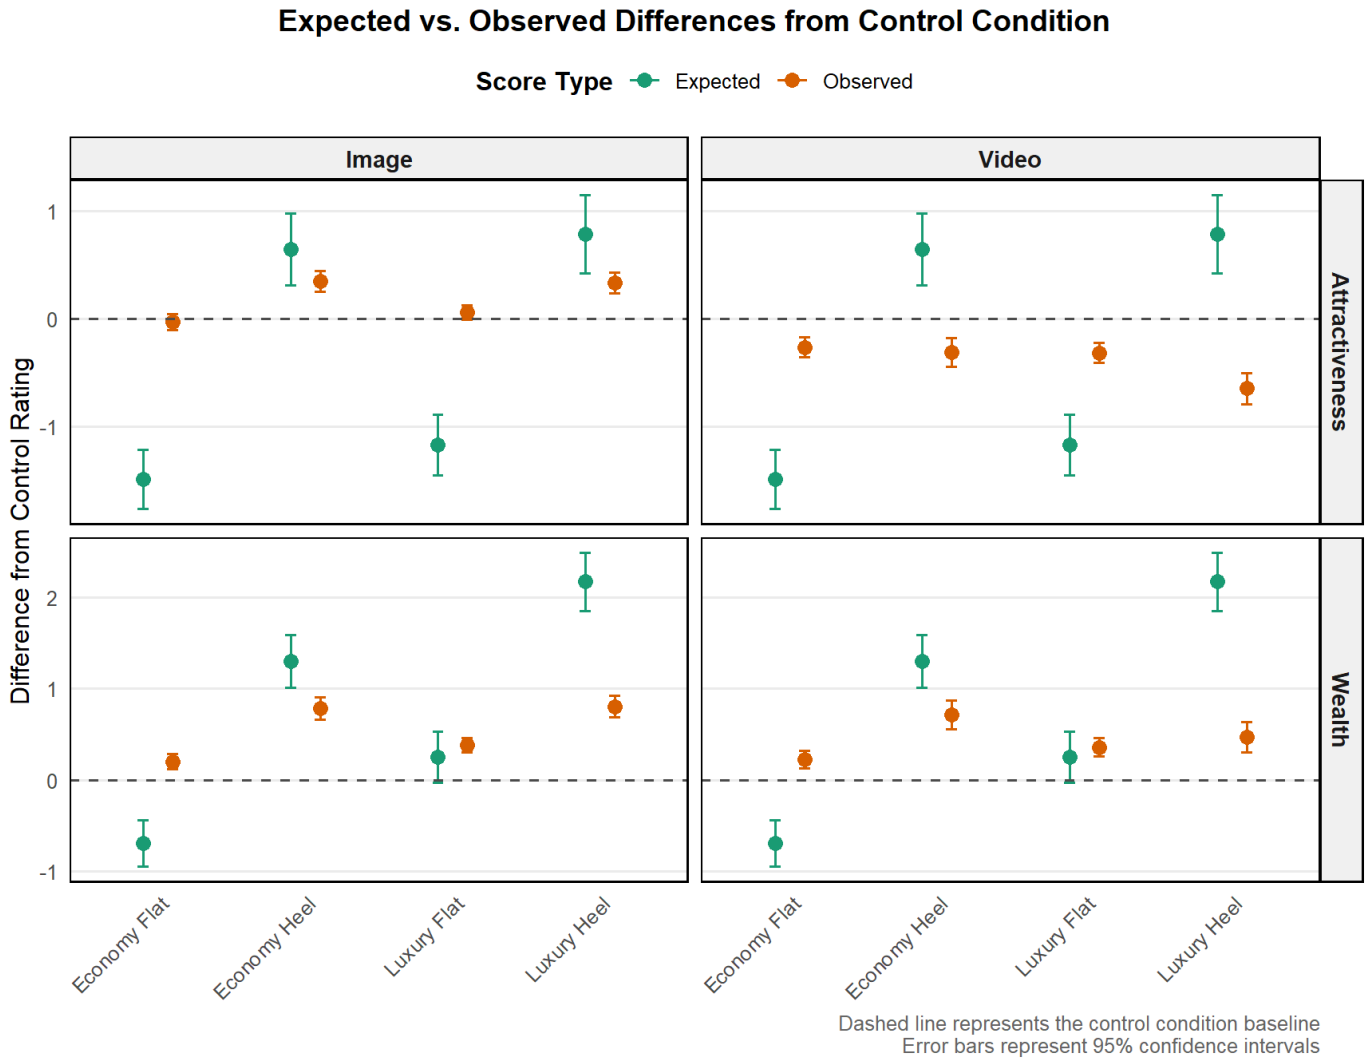

Figure B7.1. Expected (isolated item photograph) versus Observed (worn item) differences from the control condition, by footwear condition, rating dimension, and stimulus type. Error bars represent 95% confidence intervals.

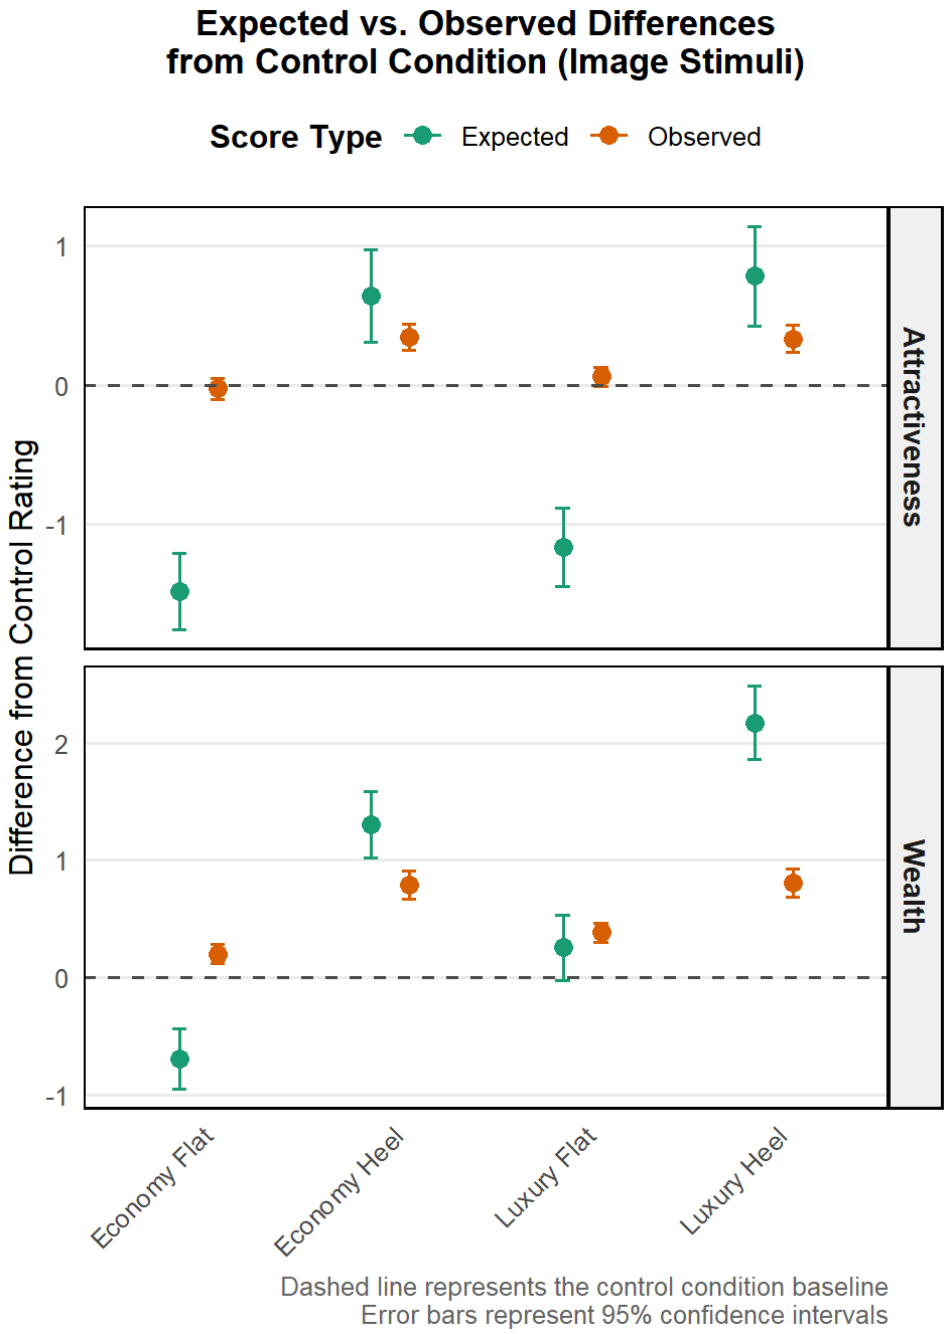

Figure B7.2. Expected versus Observed differences from the control condition, Image stimuli only. Error bars represent 95% confidence intervals.

PART VIII: Supplement B8: Walking Proficiency in the Video Stimuli

Walking proficiency was rated by three researchers, who were not blind to the study hypotheses, for each video stimulus (54 models × 5 footwear conditions = 270 videos) on a scale from 1 to 10. Ratings were collected via formr. This section assesses inter-rater reliability, aggregates the ratings to one proficiency score per video, and tests whether walking proficiency accounts for the attractiveness and wealth ratings of the video stimuli in the 2×2 factorial models (Supplement B4).

32. Data Import and Preparation of Proficiency Ratings

33. Inter-Rater Reliability
